

Estimating Mine Inflow Rates Real Time Using Analytical Methods

Christopher Scott Johnson

Sydney, Nova Scotia, Canada

Need for such a model?

- ❖ Some difficulties encountered in measuring inflow rate
 - Mine geometry
 - Inflow point not accessible
- ❖ Estimating and tracking inflow rates
 - Designing pumping systems
 - Grouting
 - Transient changes

Aquifer Response to Mine Inflow

- ❖ Mine inflow induces stress to aquifer and responds accordingly
- ❖ Mine inflows effectively handled as dewatering boundary points (e.g., pumping well, general head boundary)
- ❖ Mine inflow aquifer response and inflow prediction modeling often approached with both numerical and analytical techniques

Groundwater Flow Models

- ❖ Numerical models very powerful and able to simulate complex scenarios, but "cost" comes in setup and run time.
- ❖ Analytical models easy set up and short run times, but "cost" comes in simplicity and assumptions.

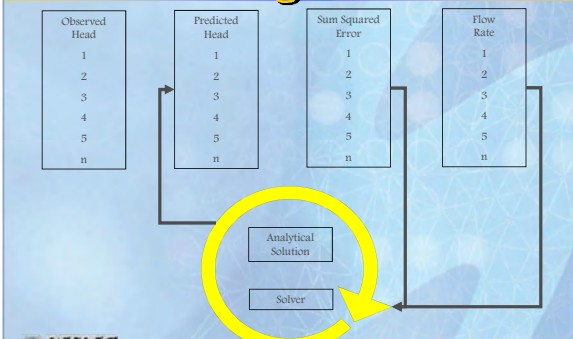

Spreadsheet Application

- ❖ Analytical solution selected
 - Application required frequent updates and therefore short run times
 - Model complexity sacrificed for speed
- ❖ This solution utilized in this case study, but other solutions have been utilized
 - Exponential Integration Approximation
- ❖ Application involved coupling This solution to a numeric solver to indirectly predict inflow

Spreadsheet Application "Flow diagram"

Observed Head	Predicted Head	Sum Squared Error	Flow Rate
1	1	1	1
2	2	2	2
3	3	3	3
4	4	4	4
5	5	5	5
n	n	n	n

The diagram illustrates a feedback loop where 'Observed Head' and 'Flow Rate' are inputs to a 'Solver'. The 'Solver' outputs 'Predicted Head', which is compared against 'Observed Head' to calculate the 'Sum Squared Error'. This error is then fed back into the 'Analytical Solution' block, which in turn provides the 'Flow Rate' to the 'Solver'.

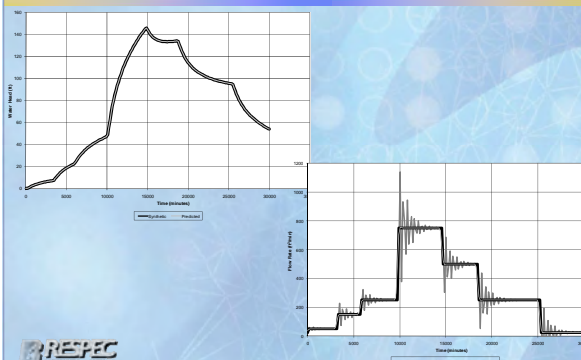

Verification

- ❖ Synthetic data set developed
 - Hydraulic properties
 - Pumping Rates
 - Radial distances to observation wells
- ❖ Forward predicted hydraulic heads with This solution in AQTESOLV
- ❖ These predicted hydraulic heads in conjunction with hydraulic properties and radial distance were used to predict pumping rates in this spreadsheet application

Verification

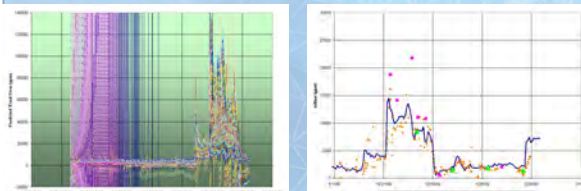

Case Study

- ❖ Mosaic K2
 - Underground potash mine
 - Mine inflow since late 1985
 - Transient inflow rates
 - Inflow into old room workings and inaccessible until rehabilitated
 - Pressure monitoring
 - Accurate flow measurements difficult in some areas
 - Grout to control and maintain inflows

Calibration

- ❖ 210 model runs
 - Optimized residual between observed and predicted inflow rate
 - Transmissivity varied from 0.15 to 60 cm²/s
 - Storage varied from 1E-3 to 5E-6 ft/ft

Spreadsheet Application

- ❖ Takes less than 10 minutes to update data and run
- ❖ Utilized at least daily and sometimes more frequently to provide real-time
- ❖ Proven itself to be reasonable estimator that can perform quickly and efficiently
- ❖ Doesn't take the place of numerical model

Acknowledgements

- ❖ Mosaic, especially Lorne Cooper, for granting permission and helping with the paper
- ❖ IMWA and CBU for putting together and hosting this conference
